

# Video Streaming with Peer-to-Peer Multicast

Alex Bikfalvi

# P2P Overlays

Peer connections between all users that participate in the network

- For streaming, the overlay is usually a tree rooted at the source
- The nodes of the tree are the peers rather than the routers
- The challenge is building a reliable multicast tree
- Usually multiple overlay trees are used

# Issues and Requirements

## Issues

- Peer behavior is unpredictable, they can join and leave at any time
- The users may experience a high delay, since the traffic is routed through several peers
- Requires complex protocol exchanges between peers in order to maintain a reliable overlay fabric

## Requirements

- NAT traversal, especially for a service that targets home users
- Consider the network heterogeneity
- Maintain a quality of experience since QoS is not usually considered in P2P
- Real time transmission, especially in communication services

# Multicast Trees

*IP Multicast*

*P2P Multicast*

- Routing and packet replication shifted to the network edge
- Same traffic traverses some links several times
- Optimized tree construction is very important
- Paramount criteria: parent selection and loop avoidance

# Multicast Trees

## Depth, Spread and Fan-Out

Depth: 3

*Maximum Depth*

Maximum Latency

*Maximum Spread*

Maximum Source  
Bandwidth

- Depth: the number of levels in the tree
- Spread: ratio between leaf and interior nodes
- Fan-out: number of children for interior nodes

# Multicast Trees

*Interior nodes and their fan-out are important*

Overlay View

Physical View

- Uplink required bandwidth can be higher than for downlink
- Downstream peer experience depends on upstream peers

# Multicast Trees

## Balanced Trees

*Interior Nodes*

$$\frac{f^d - 1}{f - 1}$$

*Leaf Nodes*

$$f^d$$

*Small Fan-Out*

*Large Fan-Out*

Fan-Out of 2

→ Around  
**50%**  
Interior Nodes

Fan-Out of 100

→ Around  
**1%**  
Interior Nodes

SplitStream

# Introduction

*Divides the video stream in several substreams called stripes*

- Use a different multicast tree for each stripe
- Distribute uniformly the peer as interior nodes in each tree
- Ideally, interior nodes in one tree are leaf nodes in all others
- The main tree where a node is interior is called proper tree

Uplink Bandwidth

Uplink = Downlink

- Downlink-uplink ratio controlled by stripes-fan-out ratio

# Routing

*Use a DHT-based P2P protocol: Pastry and Stripe*

- Assign to each peer an identifier within a range (hash space)
- Distance between two peers is the difference between IDs

## *Routing Table*

Peer ID	Address
Small distance	Many entries for closer peers
Large distance	Fewer entries for distant peers

## *The Idea*

- Assign to resources key identifiers in the hash space
- Publish the resources at peers closest to the keys
- Locate those peers using DHT routing

# Routing

## *Routing in Pastry*

# Multicast Groups

*The resources in P2P multicast are the multicast groups*

- Groups are assigned unique hash keys
- The node closer to each group key is the root for that group

*How to create interior-node disjoint multicast trees?*

- Create group keys different in most significant digits
- A group interior node should have an ID with same significant digits

# Multicast Groups

*Example: Hash space of 4 hexadecimal digits (16 bits) with 16 groups*

- Peers with node ID: 0000 to 0FFF
- Peers with node ID: 1000 to 1FFF
- Peers with node ID: F000 to FFFF
- Peers with node ID: 2000 to EFFF

# Joining and Rejection

*How to join a group?*

- Lookup the group key
- The routing should stop at first peer along the route that belongs to the group

*What happens when a node inside a group is found?*

- If the fan-out limit of the candidate parent is not reached, **adopt the new node**
- Otherwise... **reject one node**

# Joining and Rejection

*What node to reject?*

- Match criteria in the following order:
  - Children belonging to other groups
  - Children belonging to the same group and having the greatest distance to the group key

# Joining and Rejection

*What node to reject?*

- Match criteria in the following order:
  - ◉ Children belonging to other groups
  - ◉ Children belonging to the same group and having the greatest distance to the group key

# Joining and Rejection

*What node to reject?*

- Match criteria in the following order:
  - Children belonging to other groups
  - Children belonging to the same group and having the greatest distance to the group key

# Joining and Rejection

*What node to reject?*

- Match criteria in the following order:
  - ◉ Children belonging to other groups
  - ◉ Children belonging to the same group and having the greatest distance to the group key

# Joining and Rejection

*What do orphans do?*

- Search for another parent
- If none is found, search for parent in the spare capacity tree
- If none is found... **bad luck**

## Spare Capacity Tree

- A tree with all nodes that have not reached their fan-out limit

P2PCast

# Introduction

*Same principles like in SplitStream*

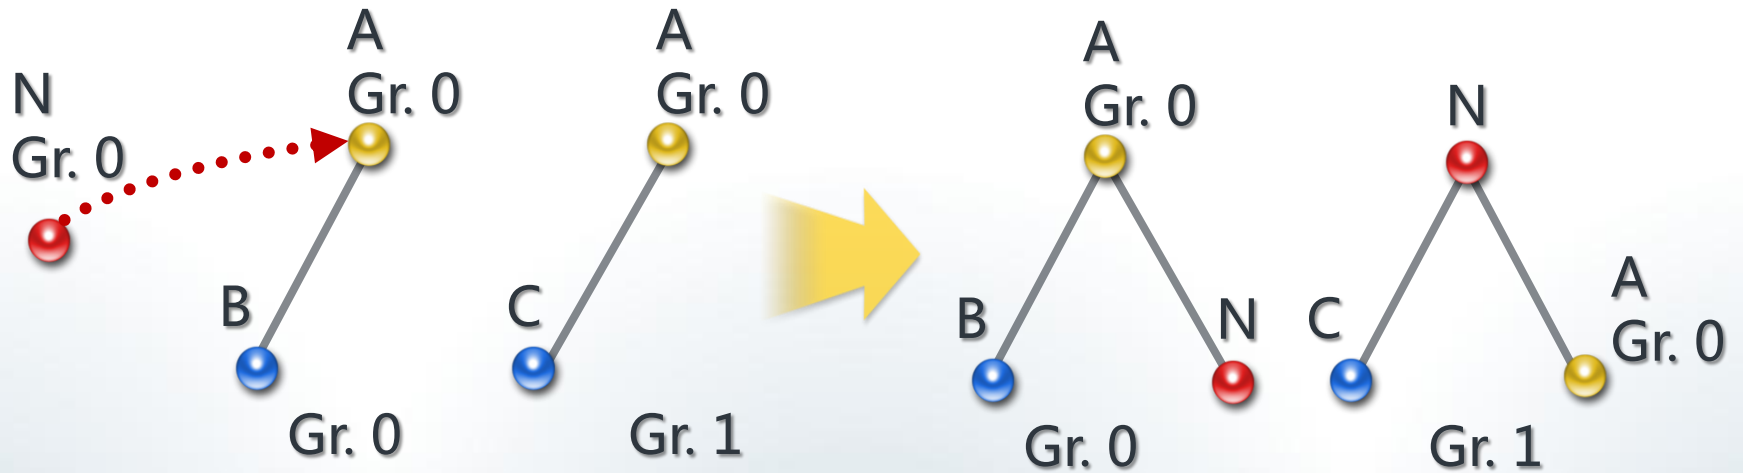

## What is Different?

- Classify the nodes in
  - ◉ Incomplete: fan-out not reached in the proper tree
  - ◉ Complete: fan-out limit reached in the proper tree
  - ◉ Only-child: a leaf node

*Let's assume an overlay with 2 tree groups and fan-out 2 for all peers*

# Joining

## *Joining an incomplete node*

## *Joining a complete node*

# Departures & Failures

*Departure of an incomplete node*

# Departures & Failures

*Departure of a complete node*

PeerCast

# Proximity Awareness

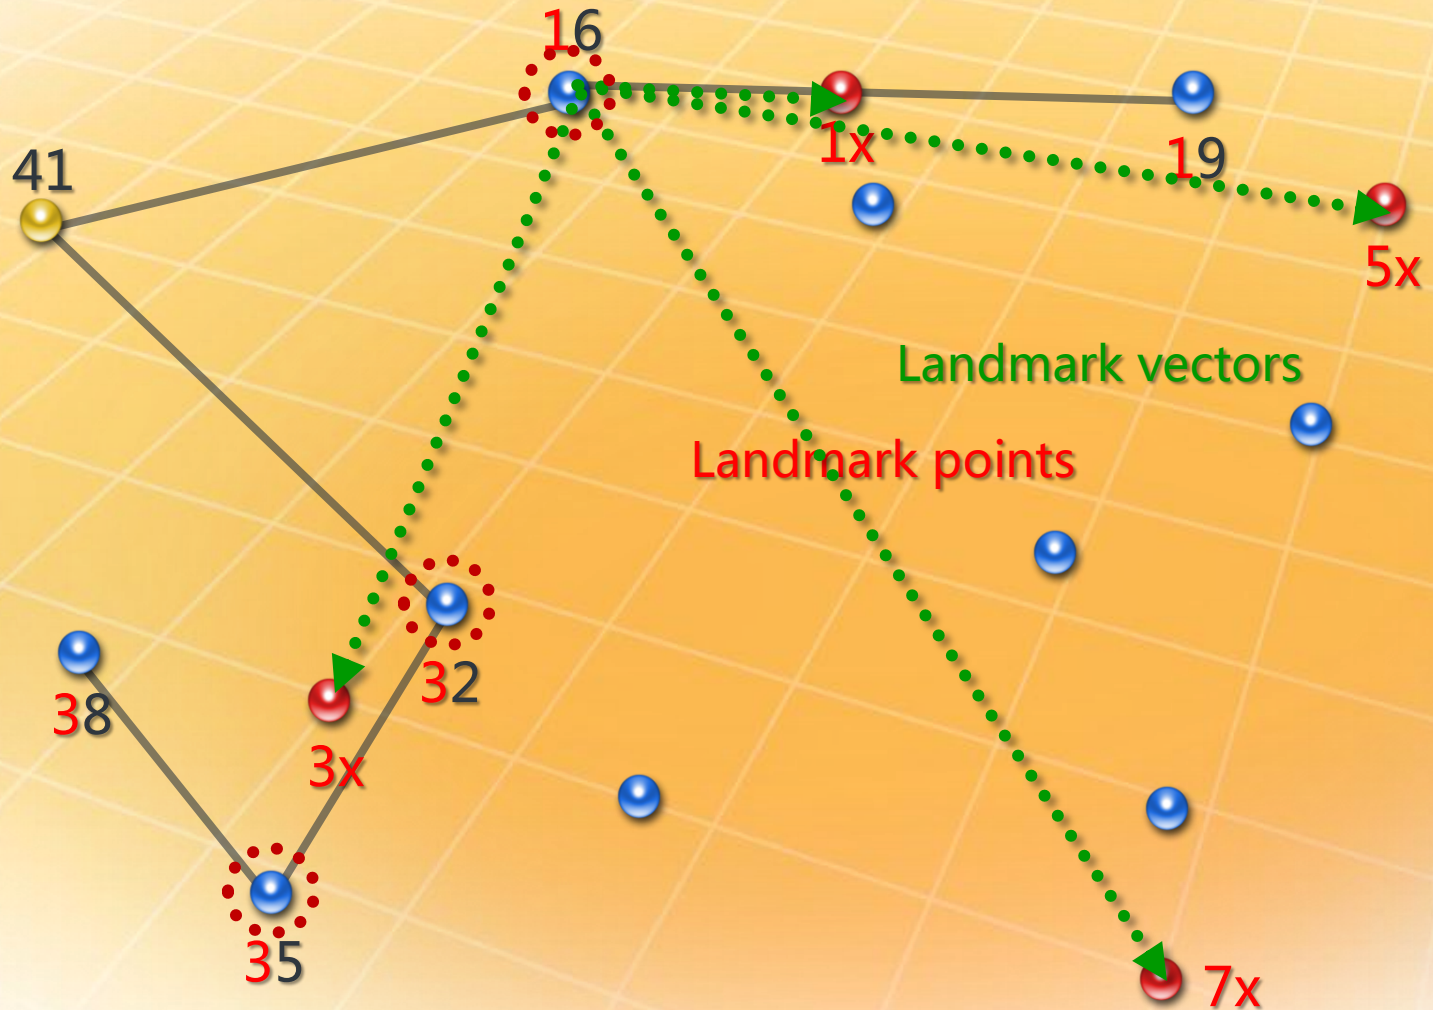

In usual DHT P2P networks...

# Proximity Awareness

PeerCast proposal...

# Multicast Management

- Service (group ID) advertised on an off-band channel
- Peer with closest ID becomes a rendezvous point
- New peers will lookup the neighbors
- Only if none of the neighbors are in the group, a lookup towards the group ID is performed

Q&A
